

# CLEANING LABORATORY EVALUATION SUMMARY

SCL #: 1999

DateRun: 05/11/1999

Experimenters: Jason Marshall

ClientType: Electron & Ion Technology Co

ProjectNumber: Project #1

Substrates: Alloys, Titanium, Alumina

PartType: Coupon

Contaminants: Cutting/Tapping Fluids, Lubricating/Lapping Oils, Oil

Cleaning Methods: Ultrasonics

Analytical Methods: Gravimetric

Purpose: To compare three cleaners effectiveness in cleaning samples using various cleaning times.

Experimental Procedure: The Alumina and Macor supplied parts were broken down into similar sized and shaped pieces to be used for the evaluation. This was performed according to proposed testing method for gravimetric analysis which states:  
Gravimetric Analysis: Employed properly, gravimetric analysis can be the most inexpensive and revealing of all surface measurement techniques. Ideally, the part or test coupon is weighed a total of three times with the same analytical balance and under the same atmospheric conditions. Weights are taken (1) before artificial contamination, (2) after artificial contamination and (3) after cleaning. These tests should be duplicated a number of times to ensure reproducibility of results. Percent soil removal and standard deviations can then be calculated. Some difficulty may arise in arriving at a pre-contamination weight under actual plant/production settings, though estimates may be possible. Care must be taken in selecting near-identical substrate pieces and applying the contaminant in a consistent manner.

All parts and pieces were subjected to a pre-cleaning protocol. The current client cleaning practice was used as this pre-cleaning method. After parts were initially weighed, they were cleaned in a 9% Branson GP solution for 30 minutes in a 40 kHz ultrasonic tank heated to 140 F. After rinsing in a tap water spray for two minutes at 120 F and dried using a Master Appliance Corp, Hot-air gun model HG-301A at 500 F for five minutes, the parts were weighed. If the cleaned weights were within 0.0009 g of the original weights, the parts were accepted as being cleaned. For the parts that did not fall within this range, additional pre-cleaning cycles were completed until the final weights were in the desired range.

Once the pre-cleaning was completed, the parts were submerged into the metal working fluid for 10 seconds and then were weighed again to determine the amount of contaminant added. Next the parts were cleaned in the specified cleaning solutions and cleaned for 10- and five-minute periods. Rinsing and drying were performed as they were in the pre-cleaning phase. Once the parts returned to room temperature, final weights were recorded and cleaning efficiencies were calculated.

SUBSTRATE MATERIAL: Molybdenum parts, Alumina pieces, Titanium parts and Macor pieces  
CONTAMINANTS: Metal working fluid (Hangsterfer's S-500CF\_US)  
CONTAMINATING PROCESS USED: Parts were immersed into contaminant for 10 seconds at room temperature.

Results: All three products removed all of the contaminant when the 10-minute cleaning cycle was used for both concentrations evaluated. Branson was effective at both dilutions and cleaning times. Brulin was effective at the lower cleaning time for the 9% solution only. Valtech was the least effective when cleaning for five minutes. Table 2 lists the cleaning efficiencies for all concentrations and times.

Table 2. Cleaning Efficiencies at 10 and 5 Minutes

Product	Branson 9	Brulin 9	Valtech	Branson 5	Brulin 5

Conclusion:

The Branson and Brulin products were nearly identical in the cleaning trials performed. The Branson product was slightly more effective at the lower concentration (5%) and time (5 min). All three products were effective in removing at least 96% of the contaminant from the parts.
